

# 3. Aggregate risk and analytical analysis

IIES lectures

---

Jeppe Druedahl

2023

# Introduction

---

- **Previously:** Non-linear transition path and perfect foresight
- **Today:**
  1. Linearized Impulse Response Function (IRF)
  2. Linearized simulation with aggregate risk
- **Literature:**
  1. Auclert et. al. (2021), »Using the Sequence-Space Jacobian to Solve and Estimate Heterogeneous-Agent Models«
  2. Auclert et. al. (2023), »The Intertemporal Keynesian Cross«
  3. Boppart et. al. (2018), »Exploiting MIT shocks in heterogeneous-agent economies: The impulse response as a numerical derivative«
  4. Documentation for GEModelTools

## IRFs and simulation

---

## Reminder of model class

- Unknowns:  $U$
- Shock:  $Z$
- Additional variables:  $X$
- Target equation system:

$$H(U, Z) = 0$$

- Auxiliary model equations:

$$X = M(U, Z)$$

- **Today:** Just consider the *first order solution*

1. Solve for IRFs for unknowns

$$H(\mathbf{U}, \mathbf{Z}) = 0 \Rightarrow \mathbf{H}_U d\mathbf{U} + \mathbf{H}_Z d\mathbf{Z} = 0 \Leftrightarrow d\mathbf{U} = \underbrace{-\mathbf{H}_U^{-1} \mathbf{H}_Z}_{\equiv \mathbf{G}_U} d\mathbf{Z}$$

2. Derive all other IRFs for

$$\begin{aligned} \mathbf{X} = \mathbf{M}(\mathbf{U}, \mathbf{Z}) &\Rightarrow d\mathbf{X} = \mathbf{M}_U d\mathbf{U} + \mathbf{M}_Z d\mathbf{Z} \\ &= \underbrace{(-\mathbf{M}_U \mathbf{H}_U^{-1} \mathbf{H}_Z + \mathbf{M}_Z)}_{\equiv \mathbf{G}} d\mathbf{Z} \end{aligned}$$

- **Computation:** Same for  $\mathbf{Z}$  as for  $\mathbf{U}$
- **Limitations:**
  1. Imprecise for *large* shocks
  2. Imprecise in models with *aggregate non-linearities*  
(direct in aggregate equations or through micro-behavior)

# Aggregate risk

- **Aggregate stochastic variables:**  $Z$  follow some known process
- **Observation:** Linearization of aggregate variables imply *certainty equivalence* with respect to these
- **Insight:** *The IRF from an MIT shock is equivalent to the IRF in a model with aggregate risk, which is linearized in the aggregate variables* (Boppart et. al., 2018)

# Comparisons

- **State-space approach with linearization:** Ahn et al. (2018); Bayer and Luetticke (2020); Bhandari et al. (2023); Bilal (2023)

## Con:

1. Harder to implement in my view
2. Valuable to be able to interpret Jacobians

## Pro:

1. More similar to standard approaches for RBC and NK models
  2. Easier path to 2nd and higher order approximations
- **Global solution:** The distribution of households is a state variable for each household  $\Rightarrow$  *explosion in complexity*
    1. Original: Krusell and Smith (1997, 1998); Algan et al. (2014);
    2. Deep learning: Fernández-Villaverde et al. (2021); Maliar et al. (2021); Han et al. (2021); Kase et al. (2022); Azinovic et al. (2022); Gu et al. (2023); Chen et al. (2023)
  - **Discrete aggregate risk:** Lin and Peruffo (2023)

# Basic linearized simulation

- **Shocks:** Write the shocks as an  $MA(\infty)$  with coefficients  $d\mathbf{Z}_s$  for  $s \in \{0, 1, \dots\}$  driven by the innovation  $\epsilon_t$ .
- **Linearized simulation** (with truncation):
  1. Draw time series of innovations,  $\tilde{\epsilon}_t$
  2. Calculate the time series of shocks as  $d\tilde{\mathbf{Z}}_t = \sum_{s=0}^{T-1} d\mathbf{Z}_s \tilde{\epsilon}_{t-s}$
  3. Calculate the time series of other aggregate variables as

$$d\tilde{\mathbf{X}}_t = \sum_{s=0}^{T-1} d\mathbf{X}_s \tilde{\epsilon}_{t-s}$$

where  $d\mathbf{X}_s$  is the IRF to a unit-shock after  $s$  periods

- **Intuition:** Sum of first order effects from all previous shocks
- **Equivalence:**
  1. Same result if we linearize all aggregated equations and write the model in  $MA(\infty)$  form
  2. The state space form can also be recovered (not needed)

# Generalized linearized simulation

- **Generality:** Add auxiliary variables (incl. distributional moments) to calculate additional IRFs and simulations
- **Full distribution:**
  1. The IRF for grid point  $i_g$  in a policy function can be calculated as

$$da_{i_g,s}^* = \sum_{s'=s}^{T-1} \sum_{X^{hh} \in \mathbf{X}^{hh}} \frac{\partial a_{i_g}^*}{\partial X_{s'-s}^{hh}} dX_{s'-s}^{hh}.$$

where  $\partial a_{i_g}^* / \partial X_k^{hh}$  is the derivative to a  $k$ -period ahead shock to input  $X^{hh}$  (calculated in fake news algorithm)

2. The policy function can there be simulated as

$$a_{i_g,t}^* = \sum_{s=0}^{T-1} da_{i_g,s}^* \tilde{\epsilon}_{t-s}$$

3. Distribution can then be simulated forwards

# Calculating moments

- **Calculating moments such as  $\text{var}(dC_t)$ :**

1. From the simulation, or
2. From the IRFs,

$$\text{var}(dC_t) = \sum_{i \in \mathcal{Z}} \sigma_i^2 \sum_{s=0}^{T-1} (dC_s^i)^2$$

where  $dC_s^i$  is the IRF to a unit-shock to  $i$  after  $s$  periods  
and  $\sigma_i$  is the standard deviation of shock  $i$

- **Covariances:**

$$\text{cov}(dX_t, dY_{t+k}) = \sum_{i \in \mathcal{Z}} \sigma_i^2 \sum_{s=0}^{T-1-k} dX_s^i dY_{s+k}^i$$

- **Covariance decomposition:**

$$\frac{\sigma_j^2 \sum_{s=0}^{T-1-k} dX_s^j dY_{s+k}^j}{\sum_{i \in \mathcal{Z}} \sigma_i^2 \sum_{s=0}^{T-1-k} dX_s^i dY_{s+k}^i}$$

- **The simplest approaches:**
  1. Impulse Response Function (IRF) matching
  2. Minimum distance / simulated method of moments (SMM)
- **Also possible:** *Bayesian likelihood estimation* (see [SSJ](#))
- **Speed:** For a new set of parameters?
  1. Only shock processes change  $\Rightarrow$  *same Jacobians* ( $\mathbf{G}_U, \mathbf{G}$ )
  2. Only need to re-compute Jacobian of aggregate variables? (only single block?)
  3. Also need to re-compute Jacobian of household problem?
  4. Also need to find stationary equilibrium again?

## Sticky wages

---

- **Household problem:**

$$v_t(z_t, a_{t-1}) = \max_{c_t} \frac{c_t^{1-\sigma}}{1-\sigma} - \varphi \frac{\ell_t^{1+\nu}}{1+\nu} + \beta \mathbb{E}_t [v_{t+1}(z_{t+1}, a_t)]$$

$$\text{s.t. } a_t + c_t = (1 + r_t^a) a_{t-1} + (1 - \tau_t) w_t \ell_t z_t + \chi_t$$

$$\log z_{t+1} = \rho_z \log z_t + \psi_{t+1}, \psi_t \sim \mathcal{N}(\mu_\psi, \sigma_\psi), \mathbb{E}[z_t] = 1$$

$$a_t \geq 0$$

- **Active decisions:** Consumption-saving,  $c_t$  (and  $a_t$ )
- **Union decision:** Labor supply,  $\ell_t$
- **Consumption function:**  $C_t^{hh} = C^{hh}(\{r_s^a, \tau_s, w_s, \ell_s, \chi_s\}_{s \geq 0})$

- **Production and profits:**

$$Y_t = \Gamma_t L_t$$

$$\Pi_t = P_t Y_t - W_t L_t$$

- **First order condition:**

$$\frac{\partial \Pi_t}{\partial L_t} = 0 \Leftrightarrow P_t \Gamma_t - W_t = 0 \Leftrightarrow w_t \equiv W_t / P_t = \Gamma_t$$

Zero profits:  $\Pi_t = 0$

- **Wage and price inflation:**

$$\pi_t^w \equiv W_t / W_{t-1} - 1$$

$$\pi_t \equiv \frac{P_t}{P_{t-1}} - 1 = \frac{W_t / \Gamma_t}{W_{t-1} / \Gamma_{t-1}} - 1 = \frac{1 + \pi_t^w}{\Gamma_t / \Gamma_{t-1}} - 1$$

- Everybody works the same:

$$\ell_t = L_t^{hh}$$

- Unspecified *wage adjustment costs* imply a **New Keynesian Wage (Phillips) Curve** (NKWPC or NKWC)

$$\pi_t^w = \kappa \left( \varphi (L_t^{hh})^\nu - \frac{1}{\mu} (1 - \tau_t) w_t (C_t^{hh})^{-\sigma} \right) + \beta \pi_{t+1}^w$$

- **Spending:**  $G_t$
- **Tax bill:**  $T_t$

$$T_t = \int \tau_t w_t \ell_t z_t d\mathbf{D}_t = \tau_t \Gamma_t L_t = \tau_t Y_t$$

- If **one-period bonds**:

$$B_t = (1 + r_t^b)B_{t-1} + G_t + \chi_t - T_t$$

- If **long-term bonds**: Geometrically declining payment stream of  $1, \delta, \delta^2, \dots$  for  $\delta \in [0, 1]$ . The bond price is  $q_t$ .

$$q_t(B_t - \delta B_{t-1}) = B_{t-1} + G_t + \chi_t - T_t$$

- Potential **tax-rule**:

$$\tau_t = \tau_{ss} + \omega q_{ss} \frac{B_{t-1} - B_{ss}}{Y_{ss}}$$

- Standard **Taylor rule**:

$$1 + i_t = (1 + i_{t-1})^{\rho_i} \left( (1 + r_{ss}) (1 + \pi_t)^{\phi_\pi} \right)^{1 - \rho_i}$$

**Alternative:** Real rate rule

$$1 + i_t = (1 + r_{ss})(1 + \pi_{t+1})$$

Indeterminacy: Consider limit or assume future tightening

- **Fisher-equation:**

$$1 + r_t = \frac{1 + i_t}{1 + \pi_{t+1}}$$

1. One-period *real* bond,  $q_t = 1$ :

$$\begin{aligned}t > 0 : r_t^b &= r_t^a = r_{t-1} \\ r_0^b &= r_0^a = 1 + r_{ss}\end{aligned}$$

2. or, one-period *nominal* bond,  $q_t = 1$ :

$$\begin{aligned}t > 0 : r_t^b &= r_t^a = r_{t-1} \\ t > 0 : r_0^b &= r_0^a = (1 + r_{ss})(1 + \pi_{ss}) / (1 + \pi_0)\end{aligned}$$

3. or, long-term (*real*) bonds:

$$\begin{aligned}\frac{1 + \delta q_{t+1}}{q_t} &= 1 + r_t \\ 1 + r_t^b &= 1 + r_t^a = \frac{1 + \delta q_t}{q_{t-1}} = \begin{cases} \frac{1 + \delta q_0}{q_{-1}} & \text{if } t = 0 \\ 1 + r_{t-1} & \text{else} \end{cases}\end{aligned}$$

# Market clearing

1. Asset market:  $q_t B_t = A_t^{hh}$
2. Labor market:  $L_t = L_t^{hh}$
3. Goods market:  $Y_t = C_t^{hh} + G_t$

# Equation system

Taylor-rule and long-term government debt:

$$\begin{bmatrix} w_t - \Gamma_t \\ Y_t - \Gamma_t L_t \\ 1 + \pi_t - \frac{1 + \pi_t^w}{\Gamma_t / \Gamma_{t-1}} \\ 1 + i_t - (1 + i_{t-1})^{\rho_i} \left( (1 + r_{ss}) (1 + \pi_t)^{\phi_\pi} \right)^{1 - \rho_i} \\ 1 + r_t - \frac{1 + i_t}{1 + \pi_{t+1}} \\ \frac{1 + \delta q_{t+1}}{q_t} - (1 + r_t) \\ 1 + r_t^a - \frac{1 + \delta q_t}{q_{t-1}} \\ \tau_t - \left[ \tau_{ss} + \omega q_{ss} \frac{B_{t-1} - B_{ss}}{Y_{ss}} \right] \\ q_t (B_t - \delta B_{t-1}) - [B_{t-1} + G_t + \chi_t - \tau_t Y_t] \\ q_t B_t - A_t^{hh} \\ \pi_t^w - \left[ \kappa \left( \varphi \left( L_t^{hh} \right)^\nu - \frac{1}{\mu} (1 - \tau_t) w_t \left( C_t^{hh} \right)^{-\sigma} \right) + \beta \pi_{t+1}^w \right] \end{bmatrix} = 0$$

# Reduced equation system with ordered blocks

$$H(\pi^w, L, G, \chi, \Gamma) = \begin{bmatrix} \pi_t^w - \left[ \kappa \left( \varphi \left( L_t^{hh} \right)^\nu - \frac{1}{\mu} (1 - \tau_t) w_t \left( C_t^{hh} \right)^{-\sigma} \right) + \beta \pi_{t+1}^w \right] \end{bmatrix} = 0$$

Production:  $w_t = \Gamma_t$

$$Y_t = \Gamma_t L_t$$

$$\pi_t = \frac{1 + \pi_t^w}{\Gamma_t / \Gamma_{t-1}} - 1$$

Central bank:  $i_t = (1 + i_{t-1})^{\rho_i} \left( (1 + r_{ss}) (1 + \pi_t)^{\phi_\pi} \right)^{1 - \rho_i} - 1$  (forwards)

$$r_t = \frac{1 + i_t}{1 + \pi_{t+1}} - 1$$

Mutual fund:  $q_t = \frac{1 + \delta q_{t+1}}{1 + r_t}$  (backwards)

$$r_t^a = \frac{1 + \delta q_t}{q_{t-1}} - 1$$

Government:  $\begin{bmatrix} \tau_t \\ B_t \end{bmatrix} = \begin{bmatrix} \tau_{ss} + \omega q_{ss} \frac{B_{t-1} - B_{ss}}{Y_{ss}} \\ \frac{(1 + \delta q_t) B_{t-1} + G_t + \chi_t - \tau_t Y_t}{q_t} \end{bmatrix}$  (forwards)

## **Analytical insights**

---

# Simpler consumption function

- **Assumptions:**

1. One-period real bond
2. No lump-sum transfers,  $\chi_t = 0$
3. Real rate rule:  $r_t = r_{ss}$
4. Fiscal policy in terms of  $dG_t$  and  $dT_t$  satisfying IBC

$$\sum_{t=0}^{\infty} (1 + r_{ss})^{-t} (dG_t - dT_t) = 0$$

- **Tax-bill:**  $T_t = \tau_t w_t \int \ell_t z_t d\mathbf{D}_t = \tau_t \Gamma_t L_t = \tau_t Y_t$
- **Household income:**  $(1 - \tau_t) w_t \ell_t z_t = \underbrace{(Y_t - T_t)}_{\equiv Z_t} z_t = Z_t z_t$
- **Consumption function:** Simplifies to

$$C_t^{hh} = C^{hh}(\{Y_s - T_s\}_{s \geq 0}) \Rightarrow \mathbf{C}^{hh} = C^{hh}(\mathbf{Y} - \mathbf{T}) = C^{hh}(\mathbf{Z})$$

## Two-equation version in $Y$ and $r$

$$Y = G + C^{hh}(r, Y - T)$$
$$r = \mathcal{R}(Y; G, T)$$

- **First equation:** Goods market clearing
- **Second equation:**
  1. Government:  $T, Y \rightarrow \tau$
  2. Resource constraint:  $G, Y \rightarrow C$
  3. Firm behavior I:  $\Gamma, Y \rightarrow L, w$
  4. NKWC:  $L, w, \tau \rightarrow \pi^w$
  5. Firm behavior II:  $\pi^w \rightarrow \pi$
  6. Central bank:  $\pi \rightarrow i$
  7. Fisher:  $i, \pi \rightarrow r$
- **Heterogeneity does not enter  $\mathcal{R}(Y; G, T)$**
- **Real rate rule:** *Inflation is a side-show*

# Intertemporal Keynesian Cross

$$\mathbf{Y} = \mathbf{G} + \mathbf{C}^{hh}(\mathbf{Y} - \mathbf{T})$$

- **Total differentiation:**

$$dY_t = dG_t + \sum_{s=0}^{\infty} \frac{\partial C_t^{hh}}{\partial Z_s} (dY_t - dT_t)$$

IBC implies:  $\sum_{t=0}^{\infty} (1 + r_{ss})^{-t} \frac{\partial C_t^{hh}}{\partial Z_s} = (1 + r_{ss})^{-s}$

- **Intertemporal Keynesian Cross** in vector form

$$\begin{aligned} d\mathbf{Y} &= d\mathbf{G} + \mathbf{M}(d\mathbf{Y} - d\mathbf{T}) \Leftrightarrow \\ (\mathbf{I} - \mathbf{M})d\mathbf{Y} &= d\mathbf{G} - \mathbf{M}d\mathbf{T} \end{aligned}$$

where  $M_{t,s} = \frac{\partial C_t^{hh}}{\partial Z_s}$  encodes the entire *complexity*

# iMPCs in the data

Figure 1: iMPCs in the Norwegian and Italian data

**Other columns:** Druedahl et al. (2023) show in micro-data that consumption responds today to news about future income.

# Perspective: Static Keynesian Cross

- **Old Keynesians:** Consumption only depends on current income

$$Y_t = G_t + C^{hh}(Y_t - T_t)$$

- **Total differentiate:**

$$\begin{aligned} dY_t &= dG_t + \frac{\partial C_t^{hh}}{\partial Z_t} (dY_t - dT_t) \\ &= dG_t + \text{mpc} \cdot (dY_t - dT_t) \end{aligned}$$

- **Solution**

$$dY_t = \frac{1}{1 - \text{mpc}} (dG_t - \text{mpc} \cdot dT_t)$$

from multiplier-process  $1 + \text{mpc} + \text{mpc}^2 \dots = \frac{1}{1 - \text{mpc}}$

# Static Keynesian Cross

figure 10-5

## An Increase in Government Purchases in the Keynesian Cross

An increase in government purchases of  $\Delta G$  raises planned expenditure by that amount for any given level of income. The equilibrium moves from point A to point B, and income rises from  $Y_1$  to  $Y_2$ . Note that the increase in income  $\Delta Y$  exceeds the increase in government purchases  $\Delta G$ . Thus, fiscal policy has a multiplied effect on income.

# Intertemporal solution technicalities

- **IBCs:**

1. NPV-vector:  $\mathbf{q} \equiv [1, (1 + r_{ss})^{-1}, (1 + r_{ss})^{-2}, \dots]'$
2. Households:  $\mathbf{q}'\mathbf{M} = \mathbf{q}'$  and  $\mathbf{q}'(\mathbf{I} - \mathbf{M}) = \mathbf{0}$
3. Government:  $\mathbf{q}'(d\mathbf{G} - d\mathbf{T}) = \mathbf{0}$

- **Problem:**  $(\mathbf{I} - \mathbf{M})^{-1}$  cannot exist because

$$\begin{aligned}(\mathbf{I} - \mathbf{M})d\mathbf{Y} &= d\mathbf{G} - \mathbf{M}d\mathbf{T} \Leftrightarrow \\ \mathbf{q}'(\mathbf{I} - \mathbf{M})d\mathbf{Y} &= \mathbf{q}'(d\mathbf{G} - d\mathbf{T}) \Leftrightarrow \\ \mathbf{0} &= \mathbf{0}\end{aligned}$$

- **Result:** If unique solution then on the form

$$\begin{aligned}d\mathbf{Y} &= \mathcal{M}(d\mathbf{G} - \mathbf{M}d\mathbf{T}) \\ \mathcal{M} &= (\mathbf{K}(\mathbf{I} - \mathbf{M}))^{-1} \mathbf{K}\end{aligned}$$

Indeterminacy: Still work-in-progress (Auclert et. al., 2023)

## Intermezzo: Response of consumption

$$d\mathbf{Y} = d\mathbf{G} + \mathbf{M}(d\mathbf{Y} - d\mathbf{T}) \Leftrightarrow$$

$$d\mathbf{Y} - d\mathbf{G} = \mathbf{M}(d\mathbf{G} - d\mathbf{T}) + \mathbf{M}(d\mathbf{Y} - d\mathbf{G}) \Leftrightarrow$$

$$d\mathbf{Y} - d\mathbf{G} = \mathcal{M}\mathbf{M}(d\mathbf{G} - d\mathbf{T}) \Leftrightarrow$$

$$d\mathbf{C} = \mathcal{M}\mathbf{M}(d\mathbf{G} - d\mathbf{T})$$

$$d\mathbf{Y} = d\mathbf{G} + \underbrace{\mathcal{M}\mathbf{M}(d\mathbf{G} - d\mathbf{T})}_{d\mathbf{C}}$$

- **Balanced budget multiplier:**

$$d\mathbf{G} = d\mathbf{T} \Rightarrow d\mathbf{Y} = d\mathbf{G}, d\mathbf{C} = 0$$

Note: Central that income and taxes affect household income proportionally in exactly the same way = no redistribution

- **Deficit multiplier:**  $d\mathbf{G} \neq d\mathbf{T}$ 
  1. Larger effect of  $d\mathbf{G}$  than  $d\mathbf{T}$
  2. *Numerical results needed*

# Fiscal multiplier

**Impact-multiplier:**

$$\frac{\partial Y_0}{\partial G_0}$$

**Cummulative-multiplier:**

$$\frac{\sum_{t=0}^{\infty} (1 + r_{ss})^{-t} dY_t}{\sum_{t=0}^{\infty} (1 + r_{ss})^{-t} dG_t}$$

# Comparison with RA model

- From lecture 1:  $\beta(1 + r_{ss}) = 1$  implies

$$C_t = (1 - \beta) \sum_{s=0}^{\infty} \beta^s Y_{t+s}^{hh} + r_{ss} a_{-1}$$

- The **iMPC-matrix** becomes

$$\mathbf{M}^{RA} = \begin{bmatrix} (1 - \beta) & (1 - \beta)\beta & (1 - \beta)\beta^2 & \cdots \\ (1 - \beta) & (1 - \beta)\beta & (1 - \beta)\beta^2 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix} = (1 - \beta)\mathbf{1}\mathbf{q}'$$

- Consumption response** is zero

$$\begin{aligned} d\mathbf{C}^{RA} &= \mathcal{M}\mathbf{M}^{RA}(d\mathbf{G} - d\mathbf{T}) \\ &= \mathcal{M}(1 - \beta)\mathbf{1}\mathbf{q}'(d\mathbf{G} - d\mathbf{T}) \\ &= \mathbf{0} \Leftrightarrow d\mathbf{Y} = d\mathbf{G} \end{aligned}$$

# Comparison with TA model

- **Hand-to-Mouth (HtM) households:**  $\lambda$  share have  $C_t = Y_t^{hh}$

$$\mathbf{M}^{TA} = (1 - \lambda)\mathbf{M}^{RA} + \lambda \mathbf{I}$$

- **Intertemporal Keynesian Cross** becomes

$$(\mathbf{I} - \mathbf{M}^{TA})d\mathbf{Y} = d\mathbf{G} - \mathbf{M}^{TA}d\mathbf{T}$$

$$(\mathbf{I} - \mathbf{M}^{RA})d\mathbf{Y} = \underbrace{\frac{1}{1 - \lambda} [d\mathbf{G} - \lambda d\mathbf{T}]}_{d\tilde{\mathbf{G}}_t} - \mathbf{M}^{RA}d\mathbf{T}$$

- **Same solution-form as RA:**  $d\mathbf{Y} = d\tilde{\mathbf{G}}_t$

$$d\mathbf{Y} = d\tilde{\mathbf{G}}_t = d\mathbf{G}_t + \frac{\lambda}{1 - \lambda} [d\mathbf{G} - d\mathbf{T}]$$

- Still a cumulative multiplier of 1 (both for RA and HtM)

Figure 2: iMPCs in the Norwegian data and several models

# Multipliers and debt-financing

Figure 5: Multipliers according to the IKC

*Note.* These figures assume a persistence of government spending equal to  $\rho_G = 0.76$ , and vary  $\rho_B$  in  $dB_t = \rho_B(dB_{t-1} + dG_t)$ . See section 7.1 for details on calibration choices.

- **Budget constraint** can be written with initial capital gain

$$a_t + c_t = (Y_t - T_t)z_t + \chi_t + \begin{cases} (1 + r_{t-1})a_{t-1} & \text{if } t > 0 \\ (1 + r_{ss} + \text{cap}_0)a_{t-1} & \text{if } t = 0 \end{cases}$$

1. Real bond:  $\text{cap}_0 = 0$
2. Nominal bond:

$$\text{cap}_0 = \frac{(1 + r_{ss})(1 + \pi_{ss})}{1 + \pi_0} - (1 + r_{ss})$$

3. Long-term bond:

$$\text{cap}_0 = \frac{1 + \delta q_0}{q_{-1}} - (1 + r_{ss})$$

- Consumption-function  $C^{hh} = C^{hh}(r, Y - T, \chi, \text{cap}_0)$  implies

$$dC^{hh} = M^r dr + M(dY - dT) + M^\chi d\chi + m^{\text{cap}} \text{cap}_0$$

where

$$M_{t,s}^r = \left[ \frac{\partial C_t^{hh}}{\partial r_s} \right], M_{t,s}^\chi = \left[ \frac{\partial C_t^{hh}}{\partial \chi_s} \right], m_t^{\text{cap}} = \left[ \frac{\partial C_t^{hh}}{\partial \text{cap}_0} \right]$$

- Why are  $M^\chi$  and  $M$  different?

## Sticky prices

---

- **Households:**
  1. Differ by stochastic idiosyncratic productivity and savings
  2. Supply labor and choose consumption
  3. Subject to a borrowing constraint
- **Intermediary goods firms** (continuum)
  1. Produce differentiated goods with labor
  2. Set price under monopolistic competition
  3. Pay dividends to households
- **Final goods firms** (representative)
  1. Produce final good with intermediary goods
  2. Take price as given under perfect competition
- **Government:**
  1. Collect taxes from households
  2. Pays interest on government debt and choose public consumption
- **Central bank:** Set nominal interest rate

# Final goods firms

- Intermediary goods indexed by  $j \in [0, 1]$
- **Static** problem for representative final good firm:

$$\max_{y_{jt} \forall j} P_t Y_t - \int_0^1 p_{jt} y_{jt} dj \text{ s.t. } Y_t = \left( \int_0^1 y_{jt}^{\frac{1}{\mu}} dj \right)^{\mu}$$

for given output price,  $P_t$ , and input prices,  $p_{jt}$

- **Demand curve** derived from FOC wrt.  $y_{jt}$

$$\forall j : y_{jt} = \left( \frac{p_{jt}}{P_t} \right)^{-\frac{\mu}{\mu-1}} Y_t$$

- **Note:** Zero profits (can be used to derive price index)

# Derivation of demand curve

- FOC wrt.  $y_{jt}$

$$0 = P_t \mu \left( \int_0^1 y_{jt}^{\frac{1}{\mu}} dj \right)^{\mu-1} \frac{1}{\mu} y_{jt}^{\frac{1}{\mu}-1} - p_{jt} \Leftrightarrow$$

$$\frac{p_{jt}}{P_t} = \left( \int_0^1 y_{jt}^{\frac{1}{\mu}} dj \right)^{\mu-1} y_{jt}^{\frac{1-\mu}{\mu}} \Leftrightarrow$$

$$\left( \frac{p_{jt}}{P_t} \right)^{\frac{\mu}{\mu-1}} = \left( \int_0^1 y_{jt}^{\frac{1}{\mu}} dj \right)^{\mu} y_{jt}^{-1} \Leftrightarrow$$

$$y_{jt} = \left( \frac{p_{jt}}{P_t} \right)^{-\frac{\mu}{\mu-1}} Y_t$$

# Intermediary goods firms

- **Dynamic problem for intermediary goods firms:**

$$J_t(p_{jt-1}) = \max_{y_{jt}, p_{jt}, n_{jt}} \left\{ \frac{p_{jt}}{P_t} y_{jt} - w_t n_{jt} - \Omega(p_{jt}, p_{jt-1}) Y_t + \frac{J_{t+1}(p_{jt})}{1 + r_{t+1}} \right\}$$

$$\text{s.t. } y_{jt} = Z_t n_{jt}, \quad y_{jt} = \left( \frac{p_{jt}}{P_t} \right)^{-\frac{\mu}{\mu-1}} Y_t$$

$$\Omega(p_{jt}, p_{jt-1}) = \frac{\mu}{\mu-1} \frac{1}{2\kappa} \left[ \log \left( \frac{p_{jt}}{p_{jt-1}} \right) \right]^2$$

- **Symmetry:** In equilibrium all firms set the same price,  $p_{jt} = P_t$
- **NKPC** derived from FOC wrt.  $p_{jt}$  and envelope condition:

$$\log(1 + \pi_t) = \kappa \left( \frac{w_t}{Z_t} - \frac{1}{\mu} \right) + \frac{Y_{t+1}}{Y_t} \frac{\log(1 + \pi_{t+1})}{1 + r_{t+1}}, \quad \pi_t \equiv P_t / P_{t-1} - 1$$

- **Implied production:**  $Y_t = y_{jt}$ ,  $N_t = n_{jt}$  (from symmetry)
- **Implied dividends:**  $d_t = Y_t - w_t N_t - \frac{\mu}{\mu-1} \frac{1}{2\kappa} [\log(1 + \pi_t)]^2 Y_t$

# Derivation of NKPC

- FOC wrt.  $p_{jt}$ :

$$0 = \left(1 - \frac{\mu}{\mu - 1}\right) \left(\frac{p_{jt}}{P_t}\right)^{-\frac{\mu}{\mu-1}} \frac{Y_t}{P_t} + \frac{\mu}{\mu - 1} \frac{w_t}{Z_t} \left(\frac{p_{jt}}{P_t}\right)^{-\frac{\mu}{\mu-1}} \frac{Y_t}{p_{jt}} \\ - \frac{\mu}{\mu - 1} \frac{1}{\kappa} \frac{\log\left(\frac{p_{jt}}{p_{jt-1}}\right)}{p_{jt}} Y_t + \frac{J'_{t+1}(p_{jt})}{1 + r_{t+1}}$$

- Envelope condition:  $J'_{t+1}(p_{jt}) = \frac{\mu}{\mu-1} \frac{1}{\kappa} \frac{\log\left(\frac{p_{jt+1}}{p_{jt}}\right)}{p_{jt}} Y_{t+1}$
- FOC + Envelope + Symmetry +  $\pi_t = P_t/P_{t-1} - 1$

$$0 = \left(1 - \frac{\mu}{\mu - 1}\right) \frac{Y_t}{P_t} + \frac{\mu}{\mu - 1} \frac{w_t}{Z_t} \frac{Y_t}{P_t} \\ + \frac{\mu}{\mu - 1} \frac{1}{\kappa} \log(1 + \pi_t) \frac{Y_t}{P_t} + \frac{\frac{\mu}{\mu-1} \frac{1}{\kappa} \log(1 + \pi_{t+1}) \frac{Y_{t+1}}{P_t}}{1 + r_{t+1}}$$

- **Household problem:** Distribution,  $\mathbf{D}_t$ , over  $z_t$  and  $a_{t-1}$

$$v_t(z_t, a_{t-1}) = \max_{c_t} \frac{c_t^{1-\sigma}}{1-\sigma} - \varphi \frac{\ell_t^{1+\nu}}{1+\nu} + \beta \mathbb{E}[v_{t+1}(z_{t+1}, a_t) | z_t, a_t]$$

$$\text{s.t. } a_t = (1 + r_t)a_{t-1} + (w_t \ell_t - \tau_t + d_t)z_t - c_t \geq 0$$

$$\log z_{t+1} = \rho_z \log z_t + \psi_{t+1}, \psi_t \sim \mathcal{N}(\mu_\psi, \sigma_\psi), \mathbb{E}[z_t] = 1$$

- **Dividends:** Distributed proportional to productivity (ad hoc)
- **Taxes:** Collected proportional to productivity (ad hoc)
- **Optimality conditions:**

$$\text{FOC wrt. } c_t : 0 = c_t^{-\sigma} - \beta \mathbb{E}_t[v_{a,t+1}(z_{t+1}, a_t)]$$

$$\text{FOC wrt. } \ell_t : 0 = w_t z_t \beta \mathbb{E}_t[v_{a,t+1}(z_{t+1}, a_t)] - \varphi \ell_t^\nu$$

$$\text{Envelope condition: } v_{a,t}(z_t, a_{t-1}) = (1 + r_t)c_t^{-\sigma}$$

- **Effective labor-supply:**  $n_t = z_t \ell_t$

- **Beginning-of-period value function:**

$$\underline{v}_{a,t}(z_{t-1}, a_{t-1}) = \mathbb{E}_t [\underline{v}_{a,t}(z_t, a_{t-1})] = \mathbb{E} [(1 + r_t)c_t^{-\sigma}]$$

- **Endogenous grid method:** Vary  $z_t$  and  $a_t$  to find

$$c_t = (\beta \underline{v}_{a,t+1}(z_t, a_t))^{-\frac{1}{\sigma}}$$

$$\ell_t = \left( \frac{w_t z_t}{\varphi} c_t^{-\sigma} \right)^{\frac{1}{\nu}}$$

$$m_t = c_t + a_t - (w_t \ell_t - \tau_t + d_t) z_t$$

- **Consumption and labor supply:** Use linear interpolation to find

$$c^*(z_t, a_{t-1}) \text{ and } \ell^*(z_t, a_{t-1}) \text{ with } m_t = (1 + r_t)a_{t-1}$$

- **Savings:**  $a^*(z_t, a_{t-1}) = (1 + r_t)a_{t-1} - c_t^* + (w_t \ell_t^* - \tau_t + d_t) z_t$

- **Problem:**  $a^*(z_t, a_{t-1}) < 0$  violate borrowing constraint
- **Refinement if  $a^*(z_t, a_{t-1}) < 0$  by:**

Find  $\ell^*$  (and  $c^*$  and  $n^*$ ) with *Newton solver* assuming  $a^* = 0$

1. Stop if  $f(\ell^*) = \ell^* - \left(\frac{w_t z_t}{\varphi}\right)^{\frac{1}{\nu}} (c^*)^{-\frac{\sigma}{\nu}} < \text{tol.}$  where

$$c^* = (1 + r_t)a_{t-1} + (w_t \ell^* - \tau_t + d_t)z_t$$

$$n^* = z_t \ell^*$$

2. Set

$$\ell^* = \frac{f(\ell^*)}{f'(\ell^*)} = \frac{f(\ell^*)}{1 - \left(\frac{w_t z_t}{\varphi}\right)^{\frac{1}{\nu}} \left(-\frac{\sigma}{\nu}\right) (c^*)^{-\frac{\sigma}{\nu}} w_t z_t}$$

3. Return to step 1

- **Monetary policy:** Follow Taylor-rule:

$$i_t = i_t^* + \phi \pi_t$$

where  $i_t^*$  is a shock

- **Fisher relationship:**

$$r_t = (1 + i_{t-1}) / (1 + \pi_t) - 1$$

- **Government:** Choose  $\tau_t$  to keep debt constant and finance exogenous public consumption

$$\tau_t = r_t B_{ss} + G_t$$

# Market clearing

1. Assets:  $B_{ss} = \int a_t^*(z_t, a_{t-1}) d\mathbf{D}_t$
2. Labor:  $N_t = \int n_t^*(z_t, a_{t-1}) d\mathbf{D}_t$  (in effective units)
3. Goods:  $Y_t = \int c_t^*(z_t, a_{t-1}) d\mathbf{D}_t + G_t + \frac{\mu}{\mu-1} \frac{1}{2\kappa} [\log(1 + \pi_t)]^2 Y_t$

## As an equation system

$$\begin{aligned} H(\pi, w, Y, i^*, Z, \underline{D}_0) &= 0 \\ \left[ \begin{array}{c} \log(1 + \pi_t) - \left[ \kappa \left( \frac{w_t}{Z_t} - \frac{1}{\mu} \right) + \frac{Y_{t+1}}{Y_t} \frac{\log(1 + \pi_{t+1})}{1 + r_{t+1}} \right] \\ N_t - \int n_t^*(z_t, a_{t-1}) d\mathbf{D}_t \\ B_{ss} - \int a_t^*(z_t, a_{t-1}) d\mathbf{D}_t \end{array} \right] &= 0 \end{aligned}$$

The rest of the model is given by

$$\mathbf{X} = \mathbf{M}(\pi, w, Y, i^*, Z)$$

# As a DAG

# Steady state

- **Chosen:**  $B_{ss}$ ,  $G_{ss}$ ,  $r_{ss}$
- **Analytically:**
  1. **Normalization:**  $Z_{ss} = N_{ss} = 1$
  2. **Zero-inflation:**  $\pi_{ss} = 0 \Rightarrow i_{ss} = i_{ss}^* = (1 + r_{ss})(1 + \pi_{ss}) - 1$
  3. **Firms:**  $Y_{ss} = Z_{ss}N_{ss}$ ,  $w_{ss} = \frac{Z_{ss}}{\mu}$  and  $d_{ss} = Y_{ss} - w_{ss}N_{ss}$
  4. **Government:**  $\tau_{ss} = r_{ss}B_{ss} + G_{ss}$
  5. **Assets:**  $A_{ss} = B_{ss}$
- **Numerically:** Choose  $\beta$  and  $\varphi$  to get market clearing

# Transmission mechanism to monetary policy shock

1. **Monetary policy shock:**  $i_t^* \downarrow \Rightarrow i_t = i_t^* + \phi\pi_t \downarrow$
2. **Real interest rate:**  $r_t = \frac{1+i_t-1}{1+\pi_t} \downarrow$
3. **Taxes:**  $\tau_t = r_t B_{ss} \downarrow$
4. **Household consumption,**  $C_t^{hh} \uparrow$ , due to  $r_t \downarrow$  and  $\tau_t \downarrow$
5. **Firms production,**  $Y_t \uparrow$ , and **labor demand,**  $N_t \uparrow$
6. **Inflation,**  $\pi_t \uparrow$ , and **wage,**  $w_t \uparrow$  and **dividends,**  $d_t \downarrow$
7. **Household labor supply,**  $N_t^{hh} \uparrow$ , due to  $w_t \uparrow$  and  $d_t \downarrow$ ,  
but dampened  $\tau_t \downarrow$
8. **Nominal rate,**  $i_t \uparrow$  due to  $\pi_t \uparrow$  implying  $r_t \uparrow$
9. **Household consumption,**  $C_t^{hh} \uparrow$ , due to  $w_t \uparrow$   
but dampened by  $d_t \downarrow$  and  $r_t \uparrow$

## Exercise

---

# Exercise

Use *HANK-sticky-wages* in sub-folder.

1. Compute *fiscal multipliers* varying:
  - 1.1 Bond maturity:  $\delta$
  - 1.2 Fiscal aggressiveness:  $\omega$
  - 1.3 Monetary aggressiveness:  $\phi_\pi$
2. Does the model match the evidence of intertemporal MPCs?  
What happens to the fiscal multiplier if the fit is improved?

# Summary

---

- **Today:**

1. Aggregate risk and linearized dynamics (IRF and simulation)
2. Calculating aggregate moments (for calibration or estimation)
3. HANK with sticky wages and/or prices
4. Intertemporal Keynesian Cross
5. Analysis of fiscal multipliers

- **Next:** Examples
